How does a resonant circuit work?

In a lumped-element resonant circuit, stored energy is transferred between an inductor, which stores magnetic energy, and a capacitor, which stores electric energy, and back again every period. Distributed resonators function the same way, exchanging energy stored in electric and magnetic forms, but with the energy stored spatially.

What is resonance in LC circuit?

The total current in the circuit is split between these two components, depending on their characteristics. In an LC circuit, resonance is a special condition that occurs when the energy stored in the inductor and the capacitor is perfectly balanced, causing the circuit to oscillate at a particular frequency.

What is the resonant frequency of LC circuit?

The resonant frequency of the LC circuit is where L is the inductance in henries, and C is the capacitance in farads. The angular frequency ω has units of radians per second. The equivalent frequency in units of hertz is

How does an LC circuit store energy?

An LC circuit, oscillating at its natural resonant frequency, can store electrical energy. See the animation. A capacitor stores energy in the electric field (E) between its plates, depending on the voltage across it, and an inductor stores energy in its magnetic field (B), depending on the current through it.

What is resonance in AC circuits?

Resonance in AC circuits implies a special frequency determined by the values of the resistance, capacitance, and inductance. For series resonance the condition of resonance is straightforward and it is characterized by minimum impedance and zero phase.

How resonant circuits are connected to the outside world?

When a resonant circuit is connected to the outside world, its total losses (let's call them R_P or G_P) are combined with the source and load resistances, R_S and R_L . For example, Here is a parallel resonant circuit (C, L and R_P) connected to the outside. The total Q of this circuit is called the loaded Q or Q_L and is given by

The LC circuit. In the limit $R \rightarrow 0$ the RLC circuit reduces to the lossless LC circuit shown on Figure 3. $S C L$

 Assuming a solution of the form $A e^{st}$ the characteristic equation is $s^2 + \frac{1}{LC} = 0$ (1.17) Where $\frac{1}{LC} = \omega_0^2$ The two roots are

A parallel RLC circuit contains a resistor (R), an inductor (L), and a capacitor (C) connected in parallel. Resonance in a parallel RLC circuit occurs when the reactive effects of the inductor and capacitor cancel each other out, resulting in a purely resistive circuit. The circuit exhibits interesting properties at resonance, such as a minimum current and a maximum ...

The resonant frequency (f_0) of the RLC circuit is the frequency at which the amplitude of the current is a maximum and the circuit would oscillate if not driven by a voltage source. By inspection, this corresponds to the angular frequency ($\omega_0 = 2\pi f_0$) at which the impedance Z in Equation ref{15.15} is a minimum, or when
